Ordinary Linear Regression

estimate parameters

In OLS, we estimate the parameters by choosing β_0, β_1 to minimize the sum of squares.

$$\min_{\beta_0, \beta_1} \sum_{i} (Y_i - (\beta_0 + \beta_1 X_i))^2$$

That is, the sum of squared differences between our prediction and the true values Y_i . For OLS, closed form solutions exist for the parameter estimates:

$$\hat{\beta}_1 = \frac{\sum_i (X_i - \bar{X})(Y_i - \bar{Y})}{\sum_i (X_i - \bar{X})^2}$$

$$\hat{\beta}_0 = \bar{Y} - \beta_1 \bar{X}$$

estimate variance

The variance of the noise ϵ is estimated based on the parameters β_0 , β_1 and the data set $\{X_i, Y_i\}$:

$$\hat{Y}_i = \hat{\beta}_0 + \hat{\beta}_1 X_i$$

$$\hat{\sigma}^2 = \frac{\sum_i (\hat{Y}_i - Y_i)^2}{n - 2}$$

Notice the denominator is n-2 – the "degrees of freedom", i.e. the number of data points minus the number of estimated parameters. This estimator is unbiased, meaning $\mathbb{E}(\hat{\sigma}^2) = \sigma^2$.

least squares vs MLE

Least squares and MLE estimation for linear regression are very similar; under the assumption of gaussian noise, they are nearly equivalent, with the only difference being the estimation of the sample variance.

$$\hat{Y}_i = \hat{\beta}_0 + \hat{\beta}_1 X_i$$

$$\hat{\sigma}_{MLE}^2 = \frac{\sum_i (\hat{Y}_i - Y_i)^2}{n}$$

Notice the difference between the MLE estimator of the sample variance and the least squares estimator of the sample variance. The MLE estimator is biased i.e. $\mathbb{E}(\hat{\sigma}^2) \neq \sigma^2$; however, the bias term decays to zero as the number of data points n increases.

residuals and their properties

The residuals are defined as $r_i = \hat{y}_i - y_i$. Of course, the loss is defined as the sum of squared residuals:

$$\sum_{i} r_{i} = 0$$

$$\sum_{i} r_{i} \cdot X_{i} = 0$$
